

APPARATUS FOR AND METHOD FOR POLISHING WORKPIECE

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an apparatus for and a method of polishing a workpiece such as a semiconductor wafer to a flat mirror finish, and more particularly to an apparatus for and a method of polishing a workpiece such as a semiconductor wafer which can control the amount of a material removed from a desired area of the workpiece by a polishing action.

2. Description of the Related Art

Recent rapid progress in semiconductor device integration demands smaller and smaller wiring patterns or interconnections and also narrower spaces between interconnections which connect active areas. One of the processes available for forming such interconnection is photolithography. Though the photolithographic process can form interconnections that are at most 0.5 μm wide, it requires that surfaces on which pattern images are to be focused by a stepper be as flat as possible because the depth of focus of the optical system is relatively small.

It is therefore necessary to make the surfaces of semiconductor wafers flat for photolithography. One customary way of flattening the surfaces of semiconductor wafers is to polish them with a polishing apparatus.

Conventionally, a polishing apparatus has a turntable and a top ring which rotate at respective individual speeds. A polishing cloth is attached to the upper surface of the turntable. A semiconductor wafer to be polished is placed on the polishing cloth and clamped between the top ring and the turntable. An abrasive liquid containing abrasive grains is supplied onto the polishing cloth and retained on the polishing cloth. During operation, the top ring exerts a certain pressure on the turntable, and the surface of the semiconductor wafer held against the polishing cloth is therefore polished to a flat mirror finish while the top ring and the turntable are rotating.

The polishing apparatus is required to have such performance that the surfaces of semiconductor wafers have a highly accurate flatness. Therefore, it is preferable that the lower end surface (the holding surface) of the top ring which holds a semiconductor wafer and the contact surface of the polishing cloth which is held in contact with the semiconductor wafer, and hence the surface of the turntable to which the polishing cloth is attached, have a highly accurate flatness, and those surfaces which are highly accurately flat have been used in the art. The lower surface of the top ring and the upper surface of the polishing cloth are parallel to each other as in the ordinal cases.

It is known that the polishing action of the polishing apparatus is affected not only by the configurations of the holding surface of the top ring and the contract surface of the polishing cloth, but also by the relative speed between the polishing cloth and the semiconductor wafer, the distribution of pressure applied to the surface of the semiconductor wafer which is being polished, the amount of the abrasive liquid on the polishing cloth, and the period of time when the polishing cloth has been used. It is considered that the surface of the semiconductor wafer can be highly accurately flat if the above factors which affect the polishing action of the polishing apparatus are equalized over the entire surface of the semiconductor wafer to be polished. The larger the size of the semiconductor wafer is, the more difficult the above factors are equalized.

However, some of the above factors can easily be equalized over the entire surface of the semiconductor wafer, but the other factors cannot be equalized. For example, the relative speed between the polishing cloth and the semiconductor wafer can easily be equalized by rotating the turntable and the top ring at the same rotational speed and in the same direction. However, it is difficult to equalize the amount of the abrasive liquid on the polishing cloth because of a centrifugal forces imposed on the abrasive liquid.

The above approach which tries to equalize all the factors affecting the polishing action, including the flatnesses of the lower end surface of the top ring and the upper surface of the polishing cloth on the turntable, over the entire surface of the semiconductor wafer to be polished poses limitations on efforts to make the polished surface of the semiconductor wafer flat, often resulting in a failure to accomplish a desired degree of flatness of the polished surface.

It has been customary to achieve a more accurate flatness by making the holding surface of the top ring concave or convex to develop a certain distribution of pressure on the surface of the semiconductor wafer for thereby correcting irregularities of the polishing action which are caused by an irregular entry of the abrasive liquid and variations in the period of time when the polishing cloth has been used.

However, various problems have arisen in the case where a specific configuration is applied to the holding surface of the top ring. Specifically, since the holding surface of the top ring is held in contact with the semiconductor wafer at all times, the holding surface of the top ring affects the polishing action continuously all the time while the semiconductor wafer is being polished. Because the configuration of the holding surface of the top ring has direct effect on the polishing action, it is highly complex to correct irregularities of the polishing action by intentionally making the holding surface of the top ring concave or convex, i.e., non-flat. If the holding surface of the top ring which has been made intentionally concave or convex is inadequate, the polished surface of the semiconductor wafer may not be made as flat as desired, or irregularities of the polishing action may not be sufficiently corrected, so that the polished surface of the semiconductor wafer may not be sufficiently flat.

In addition, inasmuch as the holding surface of the top ring is of substantially the same size as the surface of the semiconductor wafer to be polished, the holding surface of the top ring is required to be made irregular in a very small area. Because such surface processing is highly complex, it is not easy to correct irregularities of the polishing action by means of the configuration of the holding surface of the top ring.

The conventional polishing apparatuses, particularly those for polishing semiconductor wafers, are required to polish workpiece surfaces to higher flatness. There have not been available suitable means and apparatus for polishing workpieces to shapes which are intentionally not flat or for polishing workpieces such that desired localized areas of workpiece surfaces are polished to different degrees.

SUMMARY OF THE INVENTION

It is therefore an object of the present invention to provide a polishing apparatus which can easily correct irregularities of a polishing action on a workpieces such as a semiconductor wafer, and polish a workpiece with an intensive polishing action on a desired localized area thereof.

According to an aspect of the present invention, there is provided a polishing apparatus for polishing a surface of a workpiece comprising: a turntable having a polishing sur-

face thereon; a top ring for supporting the workpiece to be polished and pressing the workpiece against the polishing surface under a first pressing force, the top ring having a holding surface for holding the workpiece; a pressurized fluid source for supplying pressurized fluid; a plurality of openings provided in the holding surface of the top ring for ejecting the pressurized fluid supplied from the pressurized fluid source, a plurality of areas each having the openings being defined in the holding surface so that the pressurized fluid is selectively ejectable from the openings in the respective areas.

According to another aspect of the present invention, there is provided a method of polishing a workpiece, comprising the steps of: holding a workpiece between a polishing surface of a turntable and a holding surface of a top ring disposed above the turntable; pressing the workpiece by the top ring against the polishing surface under a first pressing force; and ejecting pressurized fluid from openings in a plurality of areas in the holding surface of the top ring toward the workpiece held by the top ring, the pressurized fluid being selectively ejectable from the openings in the respective areas; and polishing the workpiece in such a state that a pressing force applied to the workpiece by the pressurized fluid is variable in a central portion and an outer circumferential portion of the workpiece, respectively.

The above and other objects, features, and advantages of the present invention will become apparent from the following description when taken in conjunction with the accompanying drawings which illustrate preferred embodiments of the present invention by way of example.

de

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Like or corresponding parts are denoted by like or corresponding reference numerals throughout views.

FIG. 1 shows the basic principles of the present invention. As shown in FIG. 1, a top ring 1 has therein a circular first chamber C_1 at a central position thereof, an annular second

On the other hand, if the amount of a material removed from the central portion of the semiconductor wafer 4 is larger than the amount of a material removed from the outer circumferential portion of the semiconductor wafer 4, the

pressurized fluid is supplied only to the third chamber C_3 , and is not supplied to the first and second chambers C_1 and C_2 , and thus the pressurized fluid is ejected only from the outer circumferential area of the holding surface of the top ring 1.

As a result, the polishing pressure applied to the outer circumferential portion of the semiconductor wafer 4 is made larger than the central portion of the semiconductor wafer 4. Thus, insufficient polishing action at the outer circumferential portion of the semiconductor wafer can be collected, and the entire surface of the semiconductor wafer 4 can be uniformly polished.

The pressures of pressurized fluid supplied to the first chamber C_1 , the second chamber C_2 and the third chamber C_3 are changed, respectively. That is, pressurized fluid having a pressure of p_1 gf/cm² is supplied to the first chamber C_1 , pressurized fluid having a pressure of P_2 gf/cm² is supplied to the second chamber C_2 , and pressurized fluid having a pressure of p_3 gf/cm² is supplied to the third chamber C_3 , respectively. In this manner, the pressures of pressurized fluid ejected from the respective annular areas of the holding surface of the top ring 1 are varied, and the fluid which is supplied between the holding surface of the top ring 1 and the upper surface of the semiconductor wafer 4 has pressure gradient so as to be higher or lower progressively from the central area to the outer circumferential area of the semiconductor wafer 4, and hence the pressing force for pressing the semiconductor wafer 4 against the polishing cloth 6 has gradient so as to be higher or lower progressively from the central area to the outer circumferential area of the semiconductor wafer 4. Thus, irregularities of the polishing action can be sufficiently corrected, and the localized area of the semiconductor wafer 4 is prevented from being polished excessively or insufficiently.

In the present invention, the pressing force F_1 (pressure per unit area, gf/cm²) for pressing the semiconductor wafer 4 against the polishing cloth 6, and the pressing force F_2 (pressure per unit area, gf/cm²) for pressing the polishing cloth 6 are variable independently of each other. Therefore, the pressing force F_2 which is applied to the polishing cloth 6 by the presser ring 3 can be changed depending on the pressing force F_1 which is applied by the top ring 1 to press the semiconductor wafer 4 against the polishing cloth 6.

Theoretically, if the pressing force F_1 which is applied by the top ring 1 to press the semiconductor wafer 4 against the polishing cloth 6 is equal to the pressing force F_2 which is applied to the polishing cloth 6 by the presser ring 3, then the distribution of applied polishing pressures, which result from a combination of the pressing forces F_1 , F_2 , is continuous and uniform from the center of the semiconductor wafer 4 to its peripheral edge and further to an outer circumferential edge of the presser ring 3 disposed around the semiconductor wafer 4. Accordingly, the peripheral portion of the semiconductor wafer 4 is prevented from being polished excessively or insufficiently.

FIGS. 2A through 2C schematically show how the polishing cloth 6 behaves when the relationship between the pressing force F_1 and the pressing force F_2 is varied. In FIG. 2A, the pressing force F_1 is larger than the pressing force F_2 ($F_1 > F_2$). In FIG. 2B, the pressing force F_1 is nearly equal to the pressing force F_2 ($F_1 \approx F_2$). In FIG. 2C, the pressing force F_1 is smaller than the pressing force F_2 ($F_1 < F_2$).

As shown in FIGS. 2A through 2C, when the pressing force F_2 applied to the polishing cloth 6 by the presser ring 3 is progressively increased, the polishing cloth 6 pressed by the presser ring 3 is progressively compressed, thus pro-

As shown in FIG. 2A, when the pressing force F_1 is larger than the pressing force F_2 ($F_1 > F_2$), the polishing pressure applied to the peripheral portion of the semiconductor wafer 4 is larger than the polishing pressure applied to the inner region of the semiconductor wafer 47 so that the amount of a material removed from the peripheral portion of the semiconductor wafer 4 is larger than the amount of a material removed from the inner region of the semiconductor wafer 4 while the semiconductor wafer 4 is being polished.

As shown in FIG. 2B, when the pressing force F_1 is substantially equal to the pressing force F_2 ($F_1 \approx F_2$), the distribution of polishing pressures is continuous and uniform from the center of the semiconductor wafer 4 to its peripheral edge and further to the outer circumferential edge of the presser ring 3, so that the amount of a material removed from the semiconductor wafer 4 is uniform from the peripheral edge to the inner region of the semiconductor wafer 4 while the semiconductor wafer 4 is being polished.

As shown in FIG. 2C, when the pressing force F_1 is smaller than the pressing force F_2 ($F_1 < F_2$), the polishing pressure applied to the peripheral portion of the semiconductor wafer 4 is smaller than the polishing pressure applied to the inner region of the semiconductor wafer 4, so that the amount of a material removed from the peripheral edge of the semiconductor wafer 4 is smaller than the amount of a material removed from the inner region of the semiconductor wafer 4 while the semiconductor wafer 4 is being polished.

The pressing force F_1 and the pressing force F_2 can be changed independently of each other before polishing or during polishing.

As described above, according to the present invention, pressurized fluid is ejected from the holding surface of the top ring 1. At this time, the areas from which the pressurized fluid is ejected are suitably selected, and the pressing force applied to the semiconductor wafer 4 by the pressurized fluid is changed in the central portion and the outer circumferential portion of the semiconductor wafer 4, respectively, during polishing.

9

FIGS. 3A through 3C show the results of an experiment in which a semiconductor wafer was polished based on the basic principles of supply of pressurized fluid according to the present invention. The semiconductor wafer used in the experiment was an 8-inch semiconductor wafer. In the experiment, the pressing force (polishing pressure) applied to the semiconductor wafer by the top ring was a constant level of 400 gf/cm², and the supply of the pressurized fluid was controlled. FIG. 3A shows the case in which the pressurized fluid was not supplied. FIG. 3B shows the case in which the pressurized fluid is supplied only to the first chamber C₁, and FIG. 3C shows the case in which the pressurized fluid is supplied only to the third chamber C₃. The pressure of the pressurized fluid was 200 gf/cm². In each of FIGS. 3A through 3C, the horizontal axis represents a distance (mm) from the center of the semiconductor wafer, and the vertical axis represents a thickness (Å) of a material removed from a semiconductor wafer.

As shown in FIGS. 3A through 3C, the thickness of the removed material at the radial positions on the semiconductor wafer is affected by controlling the supply of the pressurized fluid. Specifically, when the pressurized fluid was not supplied, as shown in FIG. 3A, the peripheral portion of the semiconductor wafer was excessively polished. When the pressurized fluid is supplied only to the first chamber C₁ to press only the central portion of the semiconductor wafer by the pressurized fluid, as shown in FIG. 3B, the peripheral portion of the semiconductor wafer was not excessively polished and the central portion of the semiconductor wafer was slightly excessively polished. When the pressurized fluid was supplied only to the third chamber C₃ to press only the outer circumferential portion of the semiconductor wafer by the pressurized fluid, as shown in FIG. 3C, the outer circumferential portion of the semiconductor wafer was excessively polished and the central portion of the semiconductor wafer was polished insufficiently.

As described above, the experimental result shown in FIGS. 3A through 3E indicate that the amount of the material removed from the localized area of the semiconductor wafer can be adjusted by controlling supply of the pressurized fluid.

FIGS. 4A through 4E show the results of an experiment in which a semiconductor wafer was polished based on the basic principles of the present invention. The semiconductor wafer used in the experiment was an 8-inch semiconductor wafer. In the experiment, the pressing force (polishing pressure) applied to the semiconductor wafer by the top ring was a constant level of 400 gf/cm², and the pressing force applied by the presser ring was changed from 600 to 200 gf/cm² successively by decrements of 100 gf/cm². Specifically, the pressing force applied by the presser ring was 600 gf/cm² in FIG. 4A, 500 gf/cm² in FIG. 4B, 400 gf/cm² in FIG. 4C, 300 gf/cm² in FIG. 4D, and 200 gf/cm² in FIG. 4E. In each of FIGS. 4A through 4E, the horizontal axis represents a distance (mm) from the center of the semiconductor wafer, and the vertical axis represents a thickness (Å) of a material removed from the semiconductor wafer.

As shown in FIGS. 4A through 4E, the thickness of the removed material at the radial positions on the semiconductor wafer is affected when the pressing force applied by the presser ring was changed. Specifically, when the pressing force applied by the presser ring was in the range from 200 to 300 gf/cm² as shown in FIGS. 4D and 4E, the peripheral portion of the semiconductor wafer was excessively polished. When the pressing force applied by the presser ring was in the range from 400 to 500 gf/cm², as shown in FIGS. 4B and 4C, the peripheral portion of the semiconductor wafer is substantially equally polished from the peripheral edge to the inner region of the semiconductor wafer. When the pressing force applied by the presser ring was 600 gf/cm², as shown in FIG. 4A, the peripheral portion of the semiconductor wafer was polished insufficiently.

The experimental results shown in FIGS. 4A through 4E indicate that the amount of the material removed from the peripheral portion of the semiconductor wafer can be adjusted by varying the pressing force applied by the presser ring independently of the pressing force applied by the top ring. From a theoretical standpoint, the peripheral portion of the semiconductor wafer should be polished optimally when the pressing force applied by the presser ring is equal to the pressing force applied by the top ring. However, since the polishing action depends on the type of the semiconductor wafer and the polishing conditions, the pressing force applied by the presser ring is selected to be of an optimum value based on the pressing force applied by the top ring depending on the type of the semiconductor wafer and the polishing conditions.

There are demands for the removal of a larger or smaller thickness of material from the peripheral portion of the semiconductor wafer than from the inner region of the semiconductor wafer depending on the type of the semiconductor wafer. To meet such demands, the pressing force applied by the presser ring is selected to be of an optimum value based on the pressing force applied by the top ring to intentionally increase or reduce the amount of the material removed from peripheral portion of the semiconductor wafer.

FIGS. 5 through 7 show a polishing apparatus according to a first embodiment of the present invention.

As shown in FIGS. 5 and 6, a top ring 1 has therein a circular first chamber C₁ at a central position thereof, an annular second chamber C₂ disposed at a radially outer side of the first chamber C₁, and an annular third chamber C₃ disposed at a radially outer side of the first chamber C₂. The first chamber C₁ is connected to a compressed air source 24 as a pressurized fluid source through a valve V₁ and a regulator R₁, the second chamber C₂ is connected to the compressed air source 24 through a valve V₂ and a regulator R₂, and the third chamber C₃ is connected to the compressed air source 24 through a valve V₃ and a regulator R₃. The top ring 1 has a recess 1a defined in a lower surface thereof for accommodating therein a semiconductor wafer 4 which is a workpiece to be polished. An elastic pad 2 of polyurethane or the like is attached to the lower surface of the top ring 1.

The top ring 1 and the elastic pad 2 have a plurality of openings 1o and 2o, respectively, which are in registry with each other. Each of the openings 1o and 2o is communicated with any one of the first chamber C₁, the second chamber C₂, and the third chamber C₃. That is, a plurality of openings each comprising the openings 1o and 2o for ejecting pressurized fluid are defined on a holding surface of the top ring 1 for holding the semiconductor wafer 4 to be polished. Thus, three concentric annular areas A₁, A₂ and A₃ are

A presser ring 3 is disposed around the top ring 1 and is vertically movable with respect to the top ring 1. A turntable 5 with a polishing cloth 6 attached to an upper surface thereof is disposed below the top ring 1.

The top ring shaft 8 has an intermediate portion extending through and corotatably coupled to a rotatable cylinder 11 by a key (not shown), and the rotatable cylinder 11 has a pulley 12 mounted on outer circumferential surface thereof. The pulley 12 is operatively connected by a timing belt 13 to a timing pulley 15 mounted on the rotatable shaft of a top ring motor 14 which is fixedly mounted on the top ring head 9. Therefore, when the top ring motor 14 is energized, the rotatable cylinder 11 and the top ring shaft 8 are integrally rotated through the timing pulley 15, the timing belt 13 and the timing pulley 12. Thus the top ring 1 is rotated. The top ring head 9 is supported by a top ring head shaft 16 which is vertically fixed on a frame (not shown).

The presser ring 3 is corotatably, but vertically movably, coupled to the top ring 1 by a key 18. The presser ring 3 is rotatably supported by a bearing 19 which is mounted on a bearing holder 20. The bearing holder 20 is connected by vertical shafts 21 to a plurality of (three in this embodiment) circumferentially spaced presser ring air cylinders 22. The presser ring air cylinders 22 are secured to a lower surface of the top ring head 9.

The top ring air cylinder 10 and the presser ring air cylinders 22 are pneumatically connected to the compressed air source 24 through regulators R_4 and R_5 , respectively. The regulator R_4 regulates an air pressure supplied from the compressed air source 24 to the top ring air cylinder 10 to adjust the pressing force which is applied by the top ring 1 to press the semiconductor wafer 4 against the polishing cloth 6. The regulator R_5 also regulates the air pressure supplied from the compressed air source 24 to the presser ring air cylinder 22 to adjust the pressing force which is applied by the presser ring 3 to press the polishing cloth 6. The regulators R_4 and R_5 are controlled by a controller (not shown in FIG. 5).

An abrasive liquid supply nozzle 25 is positioned above the turntable 5 for supplying an abrasive liquid Q onto the polishing cloth 6 on the turntable 5.

As shown in FIG. 6, the top ring 1 has an outer circumferential annular flange 1s extending downwardly toward the turntable 5. The lower surface of the top ring 1 and the annular flange is jointly define a recess 1a for accommodating the semiconductor wafer 4 therein.

The polishing apparatus shown in FIGS. 5, 6 and 7 operates as follows: The semiconductor wafer 4 to be

polished is placed in the recess 1a and held against the elastic pad 2, and the top ring air cylinder 10 is actuated to lower the top ring 1 toward the turntable 5 until the semiconductor wafer 4 is pressed against the polishing cloth 6 on the upper surface of the rotating turntable 5. The top ring 1 and the presser ring 3 are rotated by the top ring motor 14 through the top ring shaft 8. Since the abrasive liquid Q is supplied onto the polishing cloth 6 by the abrasive liquid supply nozzle 25, the abrasive liquid Q is retained on the polishing cloth 6. Therefore, the lower surface of the semiconductor wafer 4 is polished with the abrasive liquid Q which is present between the lower surface of the semiconductor wafer 4 and the polishing cloth 6.

During polishing, compressed air is supplied from the compressed air source 24 to the first, second and third chambers C_1 , C_2 and C_3 selectively, and the supplied compressed air is ejected from the lower surface of the elastic pad 2 through the openings 1o and 2o, and is supplied between the holding surface of the top ring 1 and the upper surface of the semiconductor wafer 4. At this time, at least one of the chambers C_1 , C_2 and C_3 to which compressed air is supplied is selected, and at least one of the annular areas A_1 , A_2 and A_3 from which compressed air is ejected is selected. For example, compressed air is supplied only to the first chamber C_1 , and is not supplied to the second and third chambers C_2 and C_3 , whereby the semiconductor wafer 4 is pressed against the polishing cloth 6 by the compressed air in such a state that the polishing pressure applied to the central portion of the semiconductor wafer 4 is larger than the polishing pressure applied to outer circumferential portion of the semiconductor wafer 4. Thus, if the amount of a material removed from the outer circumferential portion of the semiconductor wafer 4 is larger than the amount of a material removed from the central portion of the semiconductor wafer 4, insufficient polishing action at the central portion of the semiconductor wafer can be corrected by utilizing the pressing action of the pressurized fluid.

On the other hand, if the amount of a material removed from the central portion of the semiconductor wafer 4 is larger than the amount of a material removed from the outer circumferential portion of the semiconductor wafer 4, the compressed air is supplied only to the third chamber C_3 , and is not supplied to the first and second chambers C_1 and C_2 , whereby the polishing pressure applied to the outer circumferential portion of the semiconductor wafer 4 is larger than the polishing pressure applied to the central portion of the semiconductor wafer 4. Thus, insufficient polishing action at the outer circumferential portion of the semiconductor wafer can be corrected, and the entire surface of the semiconductor wafer 4 can be uniformly polished.

The pressures of compressed air supplied to the first chamber C_1 , the second chamber C_2 and the third chamber C_3 are changed respectively, that is, compressed air having a pressure of p_1 gf/cm² is supplied to the first chamber C_1 , compressed air having a pressure of p_2 gf/cm² is supplied to the second chamber C_2 , and compressed air having a pressure of p_3 gf/cm² is supplied. In this manner, the compressed air which is supplied between the holding surface of the top ring 1 and the upper surface of the semiconductor wafer 4 has pressure gradient so as to be higher or lower progressively from the central area to the outer circumferential area of the semiconductor wafer 4. That is, the pressing force for pressing the semiconductor wafer 4 against the polishing cloth 6 has gradient from the central area to the outer circumferential area of the semiconductor wafer 4. Thus, irregularities of the polishing action can be sufficiently corrected and the localized area of the semiconductor wafer 4 is prevented from being polished excessively or insufficiently.

Further, in the present invention, depending on the pressing force applied by the top ring 1 actuated by the top ring air cylinder 10, the pressing force applied to the polishing cloth 6 by the presser ring 3 actuated by the presser ring air cylinders 22 is adjusted while the semiconductor wafer 4 is being polished. During the polishing process, the pressing force F_1 (see FIG. 1) which is applied by the top ring 1 to press the semiconductor wafer 4 against the polishing cloth 6 can be adjusted by the regulator R_1 , and the pressing force F_2 which is applied by the presser ring 3 to press the polishing cloth 6 can be adjusted by the regulator R_2 . Therefore, during the polishing process, the pressing force F_2 applied by the presser ring 3 to press the polishing cloth 6 can be changed depending on the pressing force F_1 applied by the top ring 1 to press the semiconductor wafer 4 against the polishing cloth 6. By adjusting the pressing force F_2 with respect to the pressing force F_1 , the distribution of polishing pressures is made continuous and uniform from the center of the semiconductor wafer 4 to its peripheral edge and further to the outer circumferential edge of the presser ring 3 disposed around the semiconductor wafer 4. Consequently, the peripheral portion of the semiconductor wafer 4 is prevented from being polished excessively or insufficiently. The semiconductor wafer 4 can thus be polished to a high quality and with a high yield.

If a larger or smaller thickness of material is to be removed from the peripheral portion of the semiconductor wafer 4 than from the inner region of the semiconductor wafer 4, then the pressing force F_2 applied by the presser ring 3 is selected to be of a suitable value based on the pressing force F_1 applied by the top ring 1 to intentionally increase or reduce the amount of a material removed from the peripheral portion of the semiconductor wafer 4.

By controlling compressed air supplied to the first, second and third chambers C_1 , C_2 and C_3 , the semiconductor wafer 4 is polished by a combination of a pressing action caused by the compressed air and a pressing action caused by the presser ring 3. Thus, insufficient polishing action in the localized area (for example, the central area or the outer circumferential area) of the semiconductor wafer can be corrected. Further, the amount of the material removed from the localized areas (for example, the central area or the outer circumferential area) can be intentionally increased or decreased. In this case, in the case where the polishing pressure at the central portion of the semiconductor wafer 4 is made larger than the polishing pressure at the outer circumferential portion of the semiconductor wafer 4, the pressing force F_2 of the presser ring 3 is made larger than the pressing force F_1 of the top ring 1. Conversely, in the case where the polishing pressure at the outer circumferential portion of the semiconductor wafer 4 is made larger than the polishing pressure at the central portion of the semiconductor wafer 4, the pressing force F_2 of the presser ring 3 is made smaller than the pressing force F_1 of the top ring 1.

In this embodiment, since the semiconductor wafer 4 is accommodated in the recess 1a of the top ring 1 and protected by the annular flange 1s, the outer circumferential surface of the semiconductor wafer 4 at its peripheral edge is not rubbed by the presser ring 3 when the presser ring 3 is vertically moved with respect to the top ring 1. Therefore, the presser ring 3 as it is vertically moved with respect to the top ring 1 does not adversely affect the polishing performance of the polishing apparatus during the polishing process.

FIG. 8 shows a polishing apparatus according to a second embodiment of the present invention. As shown in FIG. 8, a top ring 51 comprises a main body 52 and a ring member

54 detachably fixed by bolts 53 to a lower outer circumferential surface of the main body 52. The top ring 51 has a recess 51a for accommodating the semiconductor wafer 4. The recess 51a is defined by a lower surface of the main body 52 and an inner circumferential surface of the ring member 54. The semiconductor wafer 4 accommodated in the recess 51a has an upper surface held by the lower surface of the main body 52 and an outer circumferential surface held by the inner circumferential surface of the ring member 54. The presser ring 3 is vertically movably disposed around the top ring 51.

The main body 52 of the top ring 51 has therein a circular first chamber C_1 at a central position thereof, an annular second chamber C_2 disposed at a radially outer side of the first chamber C_1 , and an annular third chamber C_3 disposed at a radially outer side of the first chamber C_2 . The first chamber C_1 , the second chamber C_2 and the third chamber C_3 are connected to the compressed air source (not shown) to allow compressed air to be supplied thereto in the same manner as the embodiment in FIGS. 5 through 7. The main body 52 of the top ring 51 has a plurality of openings 52o which are communicated with the first chamber C_1 , the second chamber C_2 and the third chamber C_3 , respectively. An elastic pad 2 also has a plurality of openings 2o which are in registry with the openings 52o. Thus compressed air can be applied to the upper surface of the semiconductor wafer 4.

While the workpiece to be polished according to the present invention has been illustrated as a semiconductor wafer, it may be a glass product, a liquid crystal panel, a ceramic product, etc. Further, as pressurized fluid, pressurized liquid may be used. The top ring and the presser ring may be pressed by hydraulic cylinders rather than the illustrated air cylinders. The presser ring may be pressed by electric devices such as piezoelectric or electromagnetic devices rather than the illustrated purely mechanical devices.

As described above, the present invention offers the following advantages:

The distribution of the pressing force of the workpiece is prevented from being nonuniform at the peripheral portion of the workpiece during the polishing process, and the polishing pressures can be uniformized over the entire surface of the workpiece. Therefore, the peripheral portion of the semiconductor wafer is prevented from being polished excessively or insufficiently. The entire surface of workpiece can thus be polished to a flat mirror finish. In the case where the present invention is applied to semiconductor manufacturing processes, the semiconductor devices can be polished to a high quality. Since the peripheral portion of the semiconductor wafer can be used as products, yields of the semiconductor devices can be increased.

In the case where there are demands for the removal of a larger or smaller thickness of material from the peripheral portion of the semiconductor wafer than from the inner region of the semiconductor wafer depending on the type of the semiconductor wafer, the amount of the material removed from the peripheral portion of the semiconductor wafer can be intentionally increased or decreased. Further, the amount of the material removed from not only the peripheral portion of the semiconductor wafer but also the localized area (for example, central portion or outer circumferential portion) can be intentionally increased or decreased.

Although certain preferred embodiments of the present invention have been shown and described in detail, it should
